Anisakiasis and intestinal endometriosis: under-recognized conditions in the differential diagnosis of acute abdomen

Key words: Intestinal anisakiasis. Intestinal endometriosis. Intestinal perforation. Intestinal obstruction. Acute abdomen.

DOI: 10.17235/reed.2016.4393/2016

Dear Editor,

We report the case of a 39-year-old woman who presented at the Emergency Room with intestinal sub-occlusion.

Physical exploration found tenderness in right iliac fossa (RIF), distension, and tympanism. Lab tests revealed elevated C-reactive protein (CRP) levels in the absence of leukocytosis.

She had a similar episode two months before, with uncertain ileal biopsy results (inflammatory bowel disease [IBD] vs infectious ileitis). Computerized tomography (CT) showed ileal wall thickening with dilated loops, associated with stenosis at 7 cm from the ileocecal valve, which led to a differential diagnosis between ileitis and IBD (Fig. 1).

Following conservative management failure an urgent laparoscopy was performed, which found free-flowing feecaloid fluid and ileal perforation. Ileocecal resection via laparotomy was performed.

Pathology revealed a whitish lesion, 1.0 x 0.5 cm in size, with anisakid remnants and ileal endometriosis (Fig. 2). The definitive diagnosis was intestinal endometriosis and anisakiasis with ileal perforation.

Discussion

The pathogenesis of anisakis develops in two ways: allergic disease and direct damage to the organ wall (1).

Anisakiasis usually involves the stomach and intestinal damage is rare, hence definitive diagnosis is challenging and typically occurs after surgery for complications (2).

Treatment includes the endoscopic removal of larvae (for gastric involvement) or surgery when intestinal complications develop (3).

Endometriosis is a condition that affects up to 15% of fertile women. Intestinal involvement ranges from 3% to 37%. Small bowel involvement occurs less frequently, in 5-7% of cases (4), and diagnosis is challenging due to the location, as the condition mimics a number of bowel diseases, including IBD.
We highlight the relevance of the present case because of its challenging differential diagnosis. It was initially thought to be IBD; however, after the procedure and the subsequent pathology analysis, endometriosis and anisakiasis were diagnosed.
