LETTERS TO THE EDITOR

Adult-onset Morgagni’s hernia

Key words: Morgagni’s hernia.

Dear Editor,

We report the case of a 65-year-old male patient with Down’s syndrome and a deep venous thrombosis on anticoagulation with acenocoumarol. The case presented due to non-specific, predominantly postprandial epigastric discomfort, meteorism and aerophagia. A thoracoabdominal computed tomography (CT) scan revealed a Morgagni hernia with a cephalad migration of part of the stomach, ascending colon and transverse colon (Fig. 1). After laparotomy, the defect was repaired using a titanium mesh and the patient had a favorable outcome.

Discussion

Morgagni’s hernia is the least common of all congenital diaphragmatic hernias, with an incidence of 3% (1). As in this case, it may be associated with Down’s syndrome, Turner’s syndrome, dextrocardia, Prader-Willi syndrome and tetralogy of Fallot, among others. It is usually an incidental finding in adults and when clinical manifestations are present, these are often nonspecific, although cases with gastric outlet obstruction, respiratory distress or intestinal ischemia have been reported. The imaging technique of choice for the diagnosis of Morgagni’s hernia is thoracoabdominal CT (2). Treatment usually consists of surgery with laparotomy but a mixed thoracic and abdominal approach may also be used (3). Furthermore, a case repaired using minimally invasive robotic surgery was recently reported (4).
