ABSTRACT – Background and Objectives: Alexithymia is a personality trait that may affect the development and course of obesity and effectiveness of treatment. The aim of the study is to assess the prevalence of alexithymia in obese women beginning a weight reduction program and determine the relationships between alexithymia and anxiety, depression, and binge eating.

Methods: Obese women (n = 100; age 45 ± 13 yr) completed the following self-report inventories: Toronto Alexithymia Scale (TAS 26), Hospital Anxiety and Depression Scale (HADS), and Binge Eating Scale (BES).

Results: Alexithymia was found in 46 patients and was more frequent among women who had attained only primary and vocational education than in those with a higher education level (39.1% vs. 10.9%; p = 0.002) and in those >45 years old than in younger women (30.4% vs. 69.6%; p = 0.03). The frequency of severe depression symptoms was
higher in alexithymic women than in non-alexithymic women (19.6% vs. 5.6%; p = 0.03); however, the anxiety state was equally prevalent in both subgroups. The prevalence of alexithymia (52.6% vs. 44.4%) and its level (73.2 ± 8.9 vs. 71.2 ± 11.3 points) were similar in women with and without binge eating disorder. Multivariate mixed linear regression analysis revealed that higher body mass index was associated with primary and vocational education (odds ratio [OR] = 16.69) and severe depression symptoms (OR = 52.45), but not alexithymia.

Conclusions: In addition to severe depression and low education level, obesity may predispose for the development of alexithymia. However, alexithymia does not affect the severity of obesity in women.

Introduction

The prevalence of obesity is increasing worldwide\(^1\)\(^-\)\(^4\). It is a major health problem and an important risk factor for type 2 diabetes, hypertension, coronary artery disease, stroke, sleep apnea, and cancer\(^5\)\(^-\)\(^7\).

The etiology of obesity is complex and multidimensional, and includes genetic, environmental, social, and psychological factors. A variety of factors, including negative thoughts and feelings about oneself, relationship problems, depression, anxiety, and somatomorphic disorders are common in overweight and obese subjects and may play an important role in the development and maintenance of obesity\(^8\)\(^-\)\(^13\). Conversely, mental distress may be caused by factors associated with obesity, such as eating a restrictive diet (currently or in the past), frequent weight cycling, and binge eating episodes\(^14\). Our previous study revealed a high prevalence of depression in obese subjects starting a weight loss program, which increased with the severity of obesity\(^13\).

Alexithymia is a personality trait that may affect the development and course of obesity, concomitant mental disorders, and the effectiveness of weight reduction therapy. Alexithymia, which literally means “no words for emotions,” is characterized by the inability to identify and express emotions, an impoverished fantasy life and preference for concrete concerns\(^15\). Alexithymia also appears to play a role in the development of eating disorders, such as anorexia and bulimia nervosa\(^16\). However, the results of studies assessing the relationship between alexithymia and eating behaviors have been inconsistent\(^10\). The results of some studies suggest a bilateral relationship between alexithymia and obesity\(^19\),\(^20\). Some authors have reported that obesity favors the development of secondary alexithymia\(^21\),\(^22\), whereas others consider alexithymia a primary trait, predisposing for binge eating and obesity\(^23\),\(^24\). Finally, the high frequency of alexithymia in obese individuals has been reported to be a consequence of depression\(^23\),\(^25\).

Binge eating disorder (BED) is characterized by periods of extreme over-eating that are not followed by purging behaviors. The prevalence of BED among obese individuals seeking weight loss treatment has been estimated at 30%\(^17\). Binge eating behaviors are
sometimes observed in women who do not meet the diagnostic criteria of BED according to the Diagnostic and Statistical Manual of Mental Disorders, 4th edition.

The aim of the study is to assess the prevalence of alexithymia in obese women starting a weight reduction program and determine the relationships between alexithymia and anxiety, depression, and BED.

**Patients and methods**

We enrolled obese women without concomitant diseases and not taking any medications at the time of their first visit to the Obesity Management Clinic. A total of 100 women agreed to participate in the survey; only a few women chose not to participate. All subjects received a diagnosis of simple obesity. The study protocol was approved by the Bioethics Committee of the Medical University of Silesia. All subjects provided informed written consent to participate in the study.

Body mass and height were measured, and body mass index (BMI) was calculated by using the standard formula (kg/m²). Participants completed the following self-report inventories: Hospital Anxiety and Depression Scale (HADS), Binge Eating Scale (BES), and 26-item Toronto Alexithymia Scale (TAS 26). Polish versions of the TAS-26 and HADS, but not the BES, were previously validated in Poland.

The TAS 26, a reliable and valid measure of alexithymia, consists of 26 items divided into four subscales: 1, difficulty in distinguishing feelings and bodily sensations; 2, external thinking; 3, inability to describe emotions; and 4, paucity of fantasy. Alexithymia was defined as a total score ≥74 points.

The HADS contains two subscales, anxiety and depression, each consisting of seven items scored from 0 to 3. Out of a possible 21 points, 0-7 points were considered normal, 8-10 points considered borderline, and >11 points represented severe symptoms of anxiety and depression.

The BES is a 16-item questionnaire used to assess the presence of binge eating behavior. Each question has three or four possible responses that are each assigned a numerical value. Out of a possible 46 points, >17 points indicated non-binging, 18-26 points indicated moderate binging, and ≥27 indicated severe binging.

**Statistical analysis**

All analyses were performed using Statistica 9.0 PL software. Results are presented as mean ± standard deviation (SD) or percentages. Subjects were divided into subgroups according to BMI, TAS scores, and BES scores. Normality of distribution was assessed using the Kolmogorov-Smirnov test. Chi-square test or Mann-Whitney U test were used to compare subgroups, when appropriate. Univariate correlation coefficients were calculated according to Spearman rank-order equation. Multivariate forward logistic regression analysis using the stepwise method included factors potentially favoring the occurrence of alexithymia: BMI, age, primary and vocational education, anxiety and depression level, and presence of BED. Odds ratios (ORs) are presented with 95% confidence intervals (CI). To assess relationships between BMI and clinical parameters, a multivariate mixed linear regression model with random effect (age) was used with the backward stepwise procedure. Restricted maximum likelihood estimation was used as an optimization algorithm. Goodness of fit of the regression model was assessed with the Wald $c^2$ test. The results were considered significant with a p-value <0.05.
Results

Alexithymia

Alexithymia (TAS score ≥74 points) was found in 46/100 (46%) patients. The mean TAS score in the alexithymic patients was 80.7 ± 5.6 points. Patients with BMI ≥40 kg/m² had the highest prevalence of alexithymia and the highest mean TAS score (Table 1 and 2). A significant correlation was observed between BMI and TAS score (r = 0.21, p = 0.04).

Alexithymia was more frequently diagnosed in women who had attained only primary and vocational education than in those who had attained a higher education level (Table 1), and was more frequent in women older than 45 years compared with younger women (30.4% vs. 69.6%; p = 0.03).

Subscale 1, difficulty in distinguishing feelings and bodily sensations; Subscale 2, external thinking; Subscale 3, inability to describe emotions; Subscale 4, paucity of fantasy; BMI, body mass index; TAS, Toronto Alexithymia Scale; BED, BES, Binge Eating Scale; HADS A, Hospital Anxiety and Depression Scale anxiety subscale; HADS D, Hospital Anxiety and Depression Scale depression subscale; NS, not significant.
The factors with the greatest effect on the TAS score were the inability to describe emotions ($\beta = 1.26$; $p <0.001$) and concrete thinking ($\beta = 0.90$; $p <0.001$).

**Binge eating disorder**

BED (BES score >26 points) was found in 19/100 (19%) study subjects. Although not significant, morbidly obese women had slightly higher BES scores (Table 2). A positive correlation was observed between BMI and BES score ($r = 0.21$, $p = 0.04$).

The prevalence of BED was similar between alexithymic and non-alexithymic subgroups (21.7% vs. 16.6%, NS). Although the prevalence of alexithymia did not differ significantly between women with or without BED (52.6% vs. 44.4%; NS), those with BED reported a greater difficulty distinguishing feelings and bodily sensations ($p = 0.02$) (Table 3).

**Anxiety and depression**

Symptoms of anxiety were observed in 38/100 (38%) women, and the anxiety level was markedly higher in the morbid obese subgroup (Table 2). Frequency of anxiety was similar between the alexithymic and non-alexithymic subgroups (41.3% vs. 35.2%; NS) but was significantly higher in the BED subgroup than in the non-BED subgroup (73.7% vs. 23.5%; $p <0.001$) (Table 3).

Subscale 1, difficulty in distinguishing feelings and bodily sensations; Subscale 2, external thinking; Subscale 3, inability to describe emotions; Subscale 4, paucity of fantasy; BMI, body mass index; TAS, Toronto Alexithymia Scale; BED, binge eating disorder; BES, Binge Eating Scale; HADS A, Hospital Anxiety and Depression Scale anxiety subscale; HADS D, Hospital Anxiety and Depression Scale depression subscale.

Twelve (12%) women scored ≥11 points on the HADS depression subscale, suggesting a state of depression; nine of these subjects also had alexithymia. Thus the frequency of depression was significantly higher in the alexithymic subgroup than in the non-
alexithymic subgroup (19.6% vs. 5.6%; p = 0.03) and was higher in the BED subgroup than in the non-BED subgroup (26.3% vs. 8.6%; p = 0.03). Morbidly obese women had the highest HADS depression and anxiety scores (Table 2). Moreover, BMI was positively correlated with both anxiety (r = 0.23 p = 0.02) and depression (r = 0.24 p = 0.02).

Regression analysis

Results of logistic regression analysis showed that alexithymia was associated with depression (OR = 4.14 [1.05-16.33]), BMI (OR = 1.08 [1.01-1.16]), and primary or vocational education (OR = 3.70 [1.41-9.62]). Multiple regression analysis confirmed that depression and primary/vocational education, but not BMI, were independent predictors of alexithymia (Table 4).

The multivariate mixed linear regression model with random effect (age) revealed that primary and vocational education (OR = 16.69 [1.26-∞]) and depression (OR = 52.45 [52.45-∞], but not alexithymia, are predictors of BMI (goodness of fit, $c^2$ Wald = 10.12; p<0.01; log REML = -313) (Table 5).

Discussion

The results of our study revealed that depression and low educational level were associated with alexithymia in obese women starting weight reduction therapy; however, alexithymia was not associated with BMI.

The prevalence of alexithymia in our study population was relatively high (46%) but within the previously reported range (24.1%-52.1%)\(^{10,19,29,32,33,34}\). The frequency of this personality trait increased with severity of obesity, from 33.3% (class I obesity) to 64.3% (morbid obesity). External thinking and inability to describe emotions accounted for most of the variability in the TAS score in obese. This finding was consistent with that of a previous study, which suggested that externally oriented thinking is the most pronounced aspect of alexithymia in obese patients\(^ {35}\). A more concrete style of thinking can translate into a reduced interest in one’s own inner life, overeating, or a sedentary lifestyle. Results obtained by Helmers et al. suggest that components of alexithymia (e.g., difficulty identifying emotions) are associated with malnutrition and alcohol and drug abuse, whereas difficulty communicating emotions is associated with a sedentary lifestyle\(^ {36}\).

The association between alexithymia and morbid obesity suggests that alexithymia plays a role in further weight gain in obese individuals. However, multivariate mixed linear regression analysis failed to confirm this hypothesis, showing only the influence of depression and low educational level on the severity of obesity. These findings suggest that the higher incidence of alexithymia in patients with morbid obesity is secondary to coexisting depression, and that alexithymia appears as a temporary state in this group. A previously published study reported that alexithymia occurred more frequently in obese individuals than in those with normal weight\(^ {37}\). Thus, our findings do not exclude a direct link between alexithymia and obesity.

It should be emphasized that the prevalence of alexithymia in obese individuals is influenced by additional factors including gender, age, and education level. Consistent with the results of previously published studies, we also observed a relationship between lower education level and alexithymia\(^ {38-40}\) and a higher prevalence of alexithymia in obese women older than 45 years\(^ {41,42}\).

We further evaluated other factors (depression, anxiety, and binge eating) that could potentially influence the occurrence of alexithymia in obese individuals. We found that the prevalence of depression in our study population (12%) was lower than that of previous studies\(^ {13,43}\). This difference may be due to the different screening inventories used, with some scales detecting only severe depression. In our study, high levels of depression were more frequently found in alexithymic women than in non-alexithymic women (19.6% vs. 5.6%). Some studies have reported that alexithymia is common in depressed subjects, and Honkalampi et al.\(^ {44}\) demonstrated that severe depression is independently associated with alexithymia. However, data showing the prevalence of depression in alexithymic obese individuals are limited. Pinaquy et al. showed a positive correlation between TAS and depression score only in obese subjects without BED, suggesting the primary nature of alexithymia in subjects with BED\(^ {23}\). Additionally, Da Rose et al. reported recently that difficulties in distinguishing emotions and inability to describe emotions were associated with depression symptoms in obese individuals\(^ {45}\).

Some authors have suggested that alexithymia in obese individuals is related to BED\(^ {23,46}\), because this personality trait fre-
quently coexists with anorexia and bulimia nervosa\textsuperscript{45,47}. However, our results, which are similar to those obtained by Zwaan \textit{et al.}\textsuperscript{17} and de Chouly de Lenclave \textit{et al.}\textsuperscript{48}, did not confirm this hypothesis, because the prevalence of alexithymia and total TAS scores were similar in the BED and non-BED subgroups. On the other hand, de Zwaan \textit{et al.} and our group observed a higher level of difficulty in distinguishing between feelings and bodily sensations, a characteristic alexithymic feature, among BED subjects\textsuperscript{49}, but we did not find a higher prevalence of BED among morbidly obese women. The reason for this is unclear but may be related to other factors influencing BED development that differ among study populations (e.g., depression level and alexithymia). Thus, BED frequency may be similar among different classes of obesity because the occurrence of alexithymia is not affected by level of depression.

Our results indicate the importance of screening for alexithymia, depression, and BED in obese subjects in daily clinical practice and, when appropriate, referral for psychotherapy. Individualized cognitive-behavioral therapy may improve the effectiveness of weight loss management, at least in some patients.

The limitations of our study are its relatively small sample size and the lack of a normal-weight control group. Moreover, we recruited obese women who were seeking help with weight loss, so our study population cannot be considered a representative sample of obese individuals in the general population. Additionally, assessments of alexithymia, BED, anxiety, and depression were based on self-report inventories only. Thus, the results of our study should be considered preliminary findings.

Conclusions

In addition to severity of depression and low education level, obesity may predispose for the development of alexithymia. However, alexithymia does not affect the severity of obesity in women.
