\textbf{ABSTRACT}

Male athletes in general are subjected to the same causes of infertility as the general population, but sports practice itself may be possibly an additional infertility factor or, at least an aggravating factor for a previously existing fertility condition; on the contrary, being physically active has been hypothesized to favor hormonal and seminological processes and could be beneficial for fertility. In this relationship, the different inherent parameters of physical activity-exercise (training volume, intensity, objective, organization and frequency) are of paramount importance. Therefore, this review discusses both the negative and positive impact of physical exercise on the male reproductive potential. Clear knowledge is lacking on this topic as incongruences exist due to the fact that studies lack standardization in assessment tools or research protocols. So that future studies can reveal more information regarding exercising male fertility, we introduce a unique questionnaire developed with the intent to help standardize future studies on male fertility and exercise.

\textbf{RESUMEN}

Los atletas masculinos presentan, generalmente, las mismas causas de infertilitad que la población general; no obstante, la práctica deportiva puede ser, por sí misma, un factor de infertilitad o un factor agravante en el caso de un problema previo de fertilidad; por otra parte, se ha sugerido recientemente que ser físicamente activo puede favorecer el entorno hormonal y seminológico y, por ende, ser beneficioso para la fertilidad. En esta relación, los distintos parámetros inherentes relacionados a la actividad física y al ejercicio (volumen, intensidad, objetivo, organización y frecuencia) son de suprema importancia. Esta revisión versa sobre el impacto, tanto negativo como positivo, del ejercicio físico sobre el potencial reproductivo masculino. No existe un conocimiento consensuado sobre este tópico debido a incongruencias derivadas del hecho de que los estudios carecen de estandarización en las herramientas de evaluación y/o los protocolos de investigación. Con la finalidad de que estudios futuros puedan revelar más información sobre la fertilidad en los hombres que practican ejercicio físico, presentamos un cuestionario único desarrollado con el objetivo de ayudar a estandarizar estudios futuros que versen sobre fertilidad masculina y ejercicio.

Impacto da atividade física e do exercício sobre o potencial reprodutivo masculino: novo questionário de avaliação

**SUMÁRIO**

Atletas do sexo masculino geralmente têm as mesmas causas de infertilidade que a população em geral; contudo, o desporto em si pode ser um fator de infertilidade ou um fator agravante no caso de problema de fertilidade anterior. Além disso, recentemente, tem sido sugerido para ser fisicamente ativo pois pode promover melhorias no ambiente seminológico e hormonal e, portanto, ser benéfico para a fertilidade. Neste sentido, os diversos parâmetros inerentes relacionados à atividade física e exercício físico (volume, intensidade, finalidade, organização e frequência) são de suma importância. Este artigo trata do impacto, tanto positivo como negativo, do exercício físico sobre o potencial reprodutivo masculino. Não há conhecimento consensual sobre este tema, por causa de inconsistências decorrentes do fato de que os estudos carecem de padrãoização em ferramentas de avaliação e/ou protocolos de pesquisa. A fim de que estudos futuros possam revelar mais informações sobre a fertilidade em homens que praticam exercício, apresentamos um questionário desenvolvido para ajudar a padronizar os estudos futuros que lidam com a fertilidade masculina e o exercício.

**Introduction**

Physical activity programs improve health and the quality of life, but excessive or exhaustive exercise exposure can lead to negative side effects, with one of the most recently recognized being possible fertility issues in both females and males when training load is elevated and intense, though this is not universally recognized. Physical activity (exercise) could exert beneficial or detrimental effects depending on the several inherent exercise regimen parameters: type, intensity, volume, objective, or organization. Regrettably, there is still lack of consensus on these effects. Extensive and important work has been done assessing female athletes in this regard but this reviewed is delimited to males only.

In males where results seem more controversial, it has been observed that prolonged intensive exercise (and training) may lead to adverse effects on physiological systems, particularly, the reproductive system and fertility with alterations in reproductive hormone levels, atrophy of the testicular germinal epithelium and adverse effects on spermatogenesis changes in semen parameters including abnormal sperm morphology and reduced sperm motility.

Nevertheless, there are still many discrepancies in studies regarding the effect of exercise and physical activity on male fertility. Therefore, the aim of the present article is to review the impact of physical exercise on reproductive performance and fertility as well as to introduce a unique questionnaire that may help standardize future studies on male fertility and exercise.

**Exercise male reproductive performance and fertility**

**Hormonal alterations – endurance training**

**Negative effect**

While there is no clear consensus, acute and chronic exercise is associated with suppressed endocrine functions at the hypothalamic and testicular levels; specifically, suppression of both gonadotropin-releasing hormone (GnRH) and serum testosterone. Taking testosterone (T) as a major regulator of the hypothalamic-pituitary-testicular (HPT) axis, available studies can be included into three categories: those that do not show changes in either T (free [fT] or total [tT] T) or any of the other HPT hormones those that show changes in testosterone (fT or tT) but show changes for the other HPT hormones and those that show changes in fT or tT but there could or could not be changes, for the other HPT hormones.
Such decreased adaptability was also observed in another study as evidenced by reduced basal fT and fT/C ratio as well as an altered T response to an exercise challenge after a heavy training period of three weeks. Similarly Vinther et al. found that values, albeit within normal range, were in the lower part of the normal spectrum. Therefore, as reported by some, T and cortisol (C) are altered as a result of changes in training volume, and the values of such hormones appear related to weekly training volume.

Not only does the volume of training induce hormonal alterations, but in fact, the intensity of the exercise may also exert an influence on hormonal profile alterations. In this regard, Safarinejad and co-workers, compared moderate-intensity exercise (60% Maximal Oxygen Consumption (VO_{2max})) to high-intensity exercise (80% VO_{2max}) for a period of 12 weeks and reported alterations in hormones (returning to normal during recovery) with a decrease in T and blunted response to a Gonadotropin Releasing Hormone (GnRH) stimulation challenge in both groups but alterations being more marked in the high intensity group.

Furthermore, our research group has shown that maximal intensity exercise imposed on physically active subjects during a short period of time results in alterations in FSH, LH, prolactin (PRL), dehydroepiandrosterone and C values but no significant changes in T, progesterone and estradiol; such alterations returned to pre-training values after three days during the recovery period.

In soccer, Grandi and Celani have observed that the LH response to a GnRH-Thyrotropin Releasing Hormone (TRH) challenge test was less in the professional players as compared to non-professional players; while no significant hormone changes were observed during the training season, PRL basal levels were increased after a strenuous soccer game. In basketball, an initial transient increase in T was observed to later on decrease, along with a decrease in T/C, from mid-season on.

The evidence discussed above points to the hormonal response to exercise being affected by both by intensity and volume of training. Although the complexity in hormone feedback mechanisms and the disparity in results in the available literature demands that a consensus in study design and protocols needs to be reached. The heterogeneity observed in different studies with regards to, but not limited, the type of athlete (sedentary vs. amateur vs. professional), the type of intervention (observational vs. interventional) should be minimized.

Positive effect

Though studies analyzing long term response are scarce, imposed training loads seem to elicit an acute response with an initial increase in androgenic hormones, but when programs are sustained, often surpassing the habitual training levels of the athletes, there may be a decrease in basal levels of these hormones. Intervention with moderate intensity aerobic exercise resulted in increased serum dihydrotestosterone (DHT), in fT and SHBG and fT/C ratio in sedentary subjects. Also, Vaa bonne and colleagues have recently reported improved values for FSH, LH, T and the T/C ratio when comparing sedentary subjects to physically active subjects.

Hormonal alterations – resistance training

Resistance exercise elicits acute post-exercise hormonal responses whereas prolonged, long-term training has an effect or basal or resting concentrations. Hormonal responses after a resistance training session, depend on the load, the used muscle mass and the impact that the session may impose on the organism. Though not to be discussed here we must be aware that use and abuse of anabolic androgenic steroids may be common feature in resistance training athletes and that these compounds may alter the HPT axis and inhibit endogenous T production, which may be reversible or not depending especially on dose and time of use.

Negative effect

While an increase in the resting levels of T is common feature of chronic response to strength training, when resistance training becomes excessive, with the athlete coming close to overtraining or with persistent fatigue, T levels may even decrease from baseline.

Yet not fully elucidated such response may involve amino acid deficit and central nervous system alterations, alterations in neurotransmitters or increase in T-inhibiting hormones, and aging processes.

Positive effect

For male athletic performance, it may be beneficial to alter the levels of circulating anabolic hormones and the anabolic-catabolic ratio as testosterone, among others, is directly involved in muscle adaptation to exercise.

Generally speaking, albeit discrepancies exist, including theories that changes in hormones are not mechanistic, but a result of hemocoagulation or decreased hepatic clearance, adequately applied resistance training provokes an increase in fT and fT levels after one training session, with magnitude of changes depending on different factors such as load (intensity, volume, recovery), amount of muscle mass involved, athlete’s age, experience and performance level. The magnitude of the load used will determine the time that T levels are elevated after training.

Reproductive function – endurance training

Negative effect

Though controversy, as in hormonal studies, there is evidence that long-term exhaustive exercise seems to negatively affect sperm quality and reproductive potential.

One study reports that even up to 10% of the assessed runners exhibit severe oligospermia, yet other authors report non-existing or merely subclinical alterations due to exercise training. Increase in “round cells” has also been reported indicating a possible infectious and/or inflammatory environment. Arce and colleagues were able to, retrospectively establish a volume threshold of 100 km/wk for semen alterations to occur, as they found alterations in sperm density, motility, morphology and in vitro sperm penetration of standard cervical mucus in endurance-trained runners when compared to resistance athletes or sedentary subjects. Similarly, Safarinejad et al. observed a negative effect of training on sperm parameters, though reverting during recovery, in high-intensity training athletes when compared to moderate-intensity ones. Conversely, Hall and co-workers could not find an influence on sperm count, morphology, or motility after a period of six weeks of gradually intensified training followed by two weeks of detraining.

High-level athletes have been typically training for many years, making it difficult to establish a potential harmful training threshold (volume and/or intensity) as they normally start training at pre-or peri-pubertal years. Nevertheless, high volume cycle training seems to correlate with sperm morphology anomalies. In fact, in triathletes, a cycling volume of 300 km/wk correlates with serious degree of morphology abnormalities and possible leading to fertility impairment. Also, ultra-endurance athletes when compared to other athletes show significantly different values for the various sperm parameters with morphology showing the greatest difference, with clinical relevance (<5% normal forms).

In animal models decreased number of cells from the spermatogenic lineage at different stages of development has been observed.
with training.\textsuperscript{14,15} Some of these studies also revealed decreased levels of serum hormones, enzymes and antioxidant agents.\textsuperscript{14,15} Vaamonde et al.\textsuperscript{16} have reported exercise-related alterations in sperm which may be prevented with antioxidant agents. Vaamonde et al.\textsuperscript{17} also recently reported that, similarly to sperm morphology, cycling volume positively correlates to sperm deoxyribonucleic acid (DNA) fragmentation, also observing high correlation between training volume, sperm DNA fragmentation, percentage of morphological abnormalities and TUNEL(+) cells (unpublished data Vaamonde).

Regarding reproductive tract abnormalities, it has been reported that a soccer player exhibited testicular mal-development;\textsuperscript{54} as the athlete had cryptorchidy it is hard to establish a relationship to sports practice, however, with greater training load all other symptoms worsened. In this regard, continuous strenuous exercise has also been linked to erectile dysfunction or impotence\textsuperscript{65} as tiredness and fatigue may lead to reduced libido, especially in bicycling exercise\textsuperscript{64,66} due to microtrauma and compression on the genital area. In rats, decreased testicular, epididymal, prostatic, and seminal vesicles somatic indices have been reported as a result of exercise.\textsuperscript{15}

Positive effect

Far less studied is the positive effect of exercise or physical activity on seminal parameters. Vaamonde et al.\textsuperscript{18} reported improved semen parameters in physically active men when compared to sedentary people, such findings being supported by hormonal differences. Other studies with endurance-trained men report that average semen parameters values are usually within normal limits\textsuperscript{16} or show subclinical alterations.\textsuperscript{2,19} In this regard, significant alterations, even if subclinical, have been reported to require a certain “training volume-threshold” (~100 km/wk) before occurring.\textsuperscript{3} Also in animals similar results have been reported, not only on sperm parameters but also on testicular health.\textsuperscript{57,68}

Training load affects oxidative stress; as such, superoxide dismutase (SOD) capacity has been reported to be increased in elite athletes\textsuperscript{69} which can affect the testicular environment. Physically active men, in comparison to higher level athletes, have been shown to have higher levels of seminal antioxidant compounds and lower levels of seminal reactive oxygen species (ROS), oxidative stress and sperm DNA fragmentation.\textsuperscript{70} Erectile dysfunction has also been reported to be less common in physically active subjects (non-athletes) than in sedentary; moreover, this condition has been seen to improve as a result of unhealthy lifestyle modification like becoming physically active (minimum energy expenditure of 200 kcal/day).\textsuperscript{17}

Also in animal models it has been observed that exercise reduces markers of oxidative stress and increases antioxidant-related enzymes,\textsuperscript{70} decreasing age-related damage, especially if exercise practice begins earlier in life,\textsuperscript{72} and also decreasing DNA damage.\textsuperscript{71} Moreover, testicular atrophy, inflammation and degeneration, related to aging, is decreased in animals submitted to exercise.\textsuperscript{58}

Reproductive function – resistance training

Negative effect

Resistance training is many times intimately relate to androgenic anabolic steroid (AAS) use and regrettably little is known, if any on sperm quality as a result of resistance training without steroid use. It has been observed that the HPT axis and its hormones are altered by supraphysiologic levels of exogenous AAS and that these changes may lead to semen alterations like azoospermia, oligospermia, teratozoospermia (mainly head and mid-piece), and oftentimes testicular atrophy\textsuperscript{74,75} as evidenced by alterations in germinal epithelium, Leydig cells, among others.\textsuperscript{76}

Positive effect

No clear evidence exists of a positive effect of resistance training on semen parameters. Arce et al.\textsuperscript{7} has observed, when comparing endurance and resistance athletes, that the latter did not manifest negative alterations as seen in endurance athlete’s semen characteristics so this could be indicative that, at least, this type of training is not substantially detrimental to semen quality.

Mixed modalities

Many team sports, such as soccer, basketball and rugby, among others, because of their inherent characteristics must be considered as mixed modalities as their training is not purely endurance or resistance. Athletes participating in such sports may also be at risk for altered hormone and semen values. Exercise may be especially deleterious in case of existing pathologies like varicocele\textsuperscript{77} and the pathology may be especially aggravated in times of intensified training or competition.\textsuperscript{61} Sperm motility has also been observed to be negatively altered in some soccer players.\textsuperscript{40}

Scientific evidence seems to support the existence of a minimum level of volume, the so-called volume-threshold, for detrimental effects to take place, either hormonal or seminological.\textsuperscript{2,13} As Hackney et al.\textsuperscript{8,31} highlighted, alterations may well represent the accumulative effect, more than the acute response, of years of training load. Competition or post-competition periods, as well as periods of intensified training seem to be particularly deleterious. Some of the latest research has shown that, training intensity, and not only volume, is greatly important in this equation as well, as Vaamonde et al.\textsuperscript{78} point out with even correlation to sperm DNA damage and alteration is oxidative stress-related parameters. Nevertheless, high-load exercise seems to exert negative impact on male fertility potential, modulated by duration, volume, intensity and type of modalities, though most of the observed alterations are subclinical and revert upon ceasing or decreasing practice.

We believe many other inherent parameters of exercise training (frequency, recovery, clothing, environmental temperature, degree of muscular–skeletal damage, infections and/or inflammations) may play in to affecting reproductive function and looking at just intensity or volume is too delimiting to research designs. The final influence-effect, as in other physiological systems, will depend on the subject’s own characteristics and how well his adaptive systems are prepared for the challenge training imposes (see Fig. 1). It is important that well designed studies with standardized assessment tools regarding testing, exercise conditions and subject characteristics (fertility especially) be performed; this especially holds true for mixed modalities sports, probably the most widely practiced and the least studied in this context at this time.

In our opinion, one critical aspect necessary in this research is a more encompassing questionnaire that addresses key issues regarding exercise practice and fertility status. To this end, we have developed and included with this review a new developed instrument based upon our collective experience, to use by researchers wanting to study exercise and fertility more extensively (see Appendix 1). It is important to note that this questionnaire, if used in research, be used with the subjects’ informed consent and Ethics Committee approval.

In conclusion, awareness must be raised that exercise must be considered as a potential cause for urological and andrological male fertility problems. As such, exercise training should be assessments in males. Also, more research is needed to reflect the positive effect of moderate and low-level exercise on reproductive potential in order to make safe recommendation in lifestyle practices to help couples in achieving pregnancy.

Appendix A. INPEF (International Network on Physical Exercise and Fertility) Questionnaire for Fertility Assessment in Male Athletes

All professionals using this questionnaire must be aware that, along with the questionnaire, participants from any study need to sign an informed consent about the study/assessment and ethical guidelines must be followed. Moreover, no data or biological samples from the participants must be used without the participants’ knowledge and approval.

Dear participant, please fill in all the information you know accurately (may leave things blank if unsure). Questions and answers provide important information on potential fertility problems.

All information provided will be regarded as strictly confidential.

Name: __________________________ Date of Birth: __________________________

A. **Health.** Describe your present health. In overall, please rate as very good, good, regular, bad, very bad. State if you have any chronic or long-term illness, if so, specify which and for how long. State any medication for the past three months including the name of drug, condition used for and dose and time of use.

Health __________________________________________________________

Any chronic or long-term illness _____________________________________

Medication in the last three months ___________________________________
B. Relevant information regarding your in-utero period (when your mother was pregnant with you), birth and childhood (when possible ask your mother), including location of your mother during the whole time she was pregnant and when she gave birth. Include information on your progenitors’ history, like birthplace, smoking status (yes, no, don’t know), medical treatment your mother underwent while pregnant (yes, no, don’t know, type, length), mother’s occupation (yes, no, don’t know, type).

Your birth date and place (mm/dd/yyyy) 

Your birth was at term (40 weeks), pre-term or post-term 

Weight _____ and height _____ at birth 

Mother’s location while pregnant with you 

How long, if any, you lived there ___ years 

Mothers birthplace _______________  Fathers birthplace  ___________________________

Mothers smoking status while pregnant _______ Mother’s work while pregnant ______________

Any treatment mother underwent while pregnant ________________

First year of life and early childhood:

Any serious illness during 1st year of life, if yes, which type ________________________________

Smoking status of parents during your childhood (state yes if any or both did) _________________

C. PAST HEALTH HISTORY (there are important health conditions that may have an impact on fertility).

Any medical or surgical treatment in any or both testicles (include all information). How many, which dose if hormonal treatment, how long, age at beginning and at the end. Please refer any trauma, with swelling or hematoma to the scrotum (give dates); state if any undescended testes (either one or both, and which one) at birth that did not need treatment

_______________________________________________________________________________

Mumps as an adult. If you had mumps as adult, please state your age and whether there was any testicular complication related to such condition

_______________________________________________________________________________

Surgery for any of the following conditions: Varicocele, testicular torsion, testicular cancer, penile problems, inguinal hernia, urinary tract, scrotal conditions. Please state any of the following: yes (and when), no, don’t know, whether its been resolved

_______________________________________________________________________________

You suffer from or have been informed to have any of the following conditions (epidydimal inflammation, bladder problems, gonorrhea, chlamydia, prostate inflammation, varicocele, inguinal hernia, diabetes, thyroid problems. Please state yes (and when you were informed), no, don’t know, whether its been resolved

_______________________________________________________________________________

Sexual life: please state if satisfied or unsatisfied and if any of the following apply and how frequently (frequently, sometimes, never): low libido, erectile problems, precocious ejaculation, anejaculation (lack of), other related problem

_______________________________________________________________________________
D. Lifestyle and work

Please state present location (how long have been there). Location history of the last 2 years

____________________________________________________________________

Regarding lifestyle please state your smoking (smoker, non-smoker) status, and how long if a smoker, type and daily number of cigarettes. Please refer to your habitual drinking habits; specify whether its beer, wine or liquor. Please state daily water intake, tap or bottled and if you consume organic food.

____________________________________________________________________

Please state your education (highest academic degree and total number of years)

____________________________________________________________________

Please state if you have regularly worked for the last three months: average weekly hours, daytime or nighttime job and if the schedule is regular, total number of hours your work requires of sitting (and if this is in locomotive means), standing, walking or combination

____________________________________________________________________

At work you may be exposed to products or environments that may affect fertility, please state if any of the following apply (painting, metal cutter, metal welding, organic solvents, degreaser, pesticides, photography, nitrogen oxide, laboratory, high temperatures [above 50C/122F], radiation, stress) and the frequency of exposure (everyday, every week, rarely, never). You may add even if not in the list should you suspect it may have an effect.

____________________________________________________________________

E. Fathering history and history of partner (as previously stated all information is strictly confidential)

Please state if you have any children (number, sex and age) or have ever got someone pregnant. Please state if you have had regular sexual relations without contraceptive measures during at least one year without female partner getting pregnant
If you and your partner have been trying/have tried to conceive, please state time you had been trying, if you achieved pregnancy or if you quit. Please state if you had any fertility testing/treatment, which one, for how long and if it was successful. Please state whether your partner has any children (number, sex and age) and whether she may have any relevant feature related to health, lifestyle or work.

Finally, please feel free to add any other information you may think of interest.

</tbody>
</table>
To be answered by ALL athletes (endurance, resistance or mixed modalities)

**Observations from the athlete**

Include any observation you may deem necessary and helpful to better characterize your training program (you may indicate "competitive, professional athlete", "competitive, non-professional athlete", or "recreational athlete" or any other information of interest).

<table>
<thead>
<tr>
<th>Have you recently taken any medicine? (in the past 3 months)</th>
<th>Indicate the name of the medicine, reason for taking it, dose and time taken</th>
